### 0.1 Introduction

FINDMODEL analyzes the input alignment to decide which of a predefined collection of models of character evolution best describes the input data, using an idea first implemented in ModelTest [13].

### 0.2 Methods and Phylogenetic packages used

The input sequences are converted into FASTA format using cf, a locally developed program. If the format of the input file is not recognized by cf, FINDMODEL suggests other options for converting the sequences into FASTA format. Input sequences are then checked to ensure that they are bona fide nucleotide sequences. If the input instance is above a certain size, FINDMODEL saves the input file, asks the user for an email address and for a mnemonic for the job, and proceeds through the steps enumerated below under control of a script, at the end of which it will email the user.

All columns containing gaps are removed from the input alignments using gapstrip. The PAUP* package is used to create a distance matrix. Weighbor [3] is then used to reconstruct a tree from that distance matrix. At that point, each of the model in the chosen set (currently, a full set of 28 or a reduced set of 12) is evaluated in turn. To evaluate a model, baseml from the PAML package is used to optimize the branch lengths of the tree (the most expensive part of the computation), then the Akaike information criterion (AIC) [1] is calculated. The model with smallest AIC score is considered to be the best-fit model [13]. The program provides the user with the likelihood and AIC score for each model considered, plus the model selected and the values of its parameters. Some tools used are explained in more detail as follows.

## Contents

### 0.2.1 gapstrip

gapstrip (available at hcv.lanl.gov/content/hcv-db/GAPSTRIP/gapstrip.html), a locally developed script, removes any column in the alignment that contains one or more gap characters and thus also reduces all sequences to the same length-that of the shortest sequence.

### 0.2.2 PHYLIP

PHYLIP (available at evolution.genetics.washington.edu/phylip.html) is a widely distributed phylogeny package written by J. Felsenstein. dnadist is one of the many programs available in PHYLIP; It uses nucleotide sequences to compute a distance matrix under one of four different models of nucleotide substitution. The default model is F84 [10] and is used to run dnadist in FINDMODEL. The pairwise distance for each pair of sequences is a maximum likelihood estimate of the divergence time (total branch length) between the two sequences. We chose to use dnadist because it is widely available and works well with Weighbor.

### 0.2.3 Weighbor

Weighbor (available at www.t10.lanl.gov/billb/weighbor) is a distance-based phylogeny reconstruction method. In effect, it is a weighted version of neighborjoining [16] that gives significantly less weight to the longer distances in the distance matrix. The weights are based on variances and covariances expected in a simple Jukes-Cantor model. Weighbor is used in FINDMODEL because it is much faster than maximum likelihood, usually faster than maximum parsimony, and less sensitive than neighbor-joining to the presence of distant taxa.

## Contents

### 0.2.4 PAML (and baseml)

PAML (available at abacus.gene.ucl.ac.uk/software/paml.html) is a package for phylogenetic analyses of DNA or protein sequences by maximum likelihood. baseml carries out a maximum-likelihood analyses of nucleotide sequence evolution. The process of substitution is assumed to be stationary and Markov process models are used to describe substitutions between nucleotides. A discrete gamma model [19] is used to accommodate rate variation among sites. baseml can estimate tree topology, branch lengths, and substitution parameters, with a multitude of options, but it does not support invariant sites, in part because the estimate of the fraction of invariant sites tends to be very sensitive to the number of taxa. Since FINDMODEL uses baseml, it does not support invariant sites either-whereas ModelTest does, because PAUP*, its phylogenetic reconstruction tool, can include an estimate of the number of invariant sites.

### 0.2.5 AIC

The Akaike information criterion is a measure of fit where the best fitting model is the one with the smallest AIC value. It is defined as

$$
\begin{equation*}
A I C=-2 \ln L+2 N \tag{0.1}
\end{equation*}
$$

where $L$ is the maximum likelihood for a specific model using $N$ independently adjusted parameters within the model $[1,13]$. AIC rewards models for good fit, but imposes a penalty for extra parameters, so fitting an excessively complex model is not likely $[2,6]$. AIC allows for model selection uncertainty and model averaging and offers various other advantages over likelihood ratio tests [4].

### 0.3 Some other features of FINDMODEL

Finding the best evolutionary model is a computationally intensive procedure, both in its original implementation as the Modeltest PAUP script and in the FINDMODEL implementation.

- FINDMODEL can find the best-fit model among twenty-eight models-see Table 0.1 (note that a $\Gamma$ deviation can be added to all model). However, in order to reduce the computational burden on the server, a default run uses a reduced set of twelve models (models in bold font in Table 0.1 and those models with $\Gamma$ ); the full set of models can be run as an option.
- Our running-time tests have been conducted on sequences of around 10,000 amino acids. These tests show that, on the current server, FINDMODEL takes 24 h to run for the full set of models on an input file of about 355 kB or for the reduced set of models on an input file of about 520 kB . Shorter se-

## Contents

quences actually slow down the process as they require more iterations in the likelihood computations. Accordingly, we set a threshold of 350 kB for the full set of models and 500 kB for the reduced set of models for the maximum input size. (We are planning to release a down-loadable version that will enable users to run on their own machines for as long as desired.)

- Input files larger than 3 kB for the full set of models or 6 kB for the reduced set of models may take over 5 minutes to complete. We used these sizes as thresholds to classify jobs as interactive or batch-mode. When the file size exceeds the threshold, the job is run in the background and the results stored for one week on the server from where they can be retrieved at an address provided in the email sent to the user upon completion of the analyses. A rough estimate of the anticipated running time is given before the job runs in this case.
- When the result is showed instantly on the web, FINDMODEL shows the parameter matrix for the selected model on its result page, and the parameter matrix for another other models considered can be showed on the same page by clicking the model name.

### 0.4 Experimental Setup

To test the performance of FINDMODEL, we generated sets of simulated DNA sequences under selected models of nucleotide substitution and compared the predictions made by FINDMODEL on these sets of sequences with the actual model used to generate them. Simulated data were generated with Seq-Gen 1.3.1 [14], which simulates the evolution of an "ancestral" sequence down the edges of a phylogenetic tree using any one of a large variety of models of nucleotide substitution. Relative state frequencies, transition to transversion ratio, and general reversible rate matrix may all be be specified, as well as site-specific rate heterogeneity. The tree used was

## Contents

Table 0.2: Parameters for tests of the JC and K2P models

| model | test \# | sequence <br> length | transition to <br> transversion |
| :---: | :---: | ---: | :---: |
| JC | 1 | 329 |  |
|  | 2 | 1,000 |  |
|  | 1 | 329 | 1.0 |
| K2P | 2 | 329 | 2.0 |
|  | 3 | 1,000 | 2.0 |

generated using Treemaker from the HCV database [11] with its sample input; this tree has 16 leaves and is relatively balanced. All tests were done with the reduced set of models.

We generated simulated DNA sequences under four different models chosen from the reduced set of models in Table 0.1: Jukes-Cantor (JC) [8], Kimura 2-parameter (K2P) [9], Hasegawa-Kishino-Yano (HKY) [7], and General Time-Reversible (G- TR) [15]. We chose these four models because they all have an obvious biological interpretation and because they span all complexity levels, from the simplest (JC) to the most complex (GTR). For each model, we simulated sequences of 329 and 1000 nucleotides in order to test the sensitivity of FINDMODEL to the length of the sequences. Transition-to-transversion ratios of 1.0 and 2.0 were used for models K2P and HKY. JC is a special case of K2P and corresponds to K2P with transition-totransversion ratio of 0.5 . The ratio 2.0 was used for more tests than 1.0 , since it is closer to the real transition-to-transversion ratio for hepatitis C sequences-our original application. Relative state frequencies, which represents the equilibrium frequencies of the four nucleotides, were calculated from real hepatitis C or HIV sequences.

Seq-Gen implements site-specific rate heterogeneity, under which different sites evolve at different rates. A particularly simple way to specify such heterogeneity is to use a gamma distribution, usually considered the most appropriate approximation

## Contents

| G |  |  | 0.579553 |

for rate differences among the variable sites [2]. A shape parameter, $\alpha$, for the $\Gamma$ rate heterogeneity must be specified, with lower values denoting more variation across sites. Typical values estimated from real data tend to be around 0.3 , so we used value of 0.1 and 0.5 in order to test the effect of large and small variations across sites.

### 0.5 Results

Our tests show that FINDMODEL results are quite accurate, since it picked the correct model (sometimes plus $\Gamma$ ) in $82 \%$ of the cases and since the AIC error rates (see Table 0.5 for explaination) in the other $18 \%$ are always below $0.12 \%$ (and mostly below $0.05 \%$ ).

### 0.5.1 Results Regarding Models

Table 0.5 summarizes the results in terms of model matches and mismatches; we report the results separately for each of the 5 instances generated for each of the 17 distinct groups of parameters.

These results can be viewed as follows:

- JC, the most specific model, was selected in 6 out of 10 test instances for JC (see Table 0.6 and Table 0.7).
- K2P was selected in 12 out of 15 test instances for K2P (see Table 0.8 to Table 0.10); of the other three test instances, only one selected a more general model $(\mathrm{HKY}+\Gamma)$, while two selected $\mathrm{K} 2 \mathrm{P}+\Gamma$.
- HKY was selected in 11 out of 20 test instances for HKY (see Table 0.11 to Table 0.14); of the other nine test instances, one selected a more general model (GTR), one selected a more specific model (K2P), four selected TrN (very similar to HKY [18]), while three selected HKY $+\Gamma$.
- HKY $+\Gamma$ was selected in 10 out of 15 tests for $H K Y+\Gamma$ (see Table 0.15 to Table 0.17); of the other five test instances, three selected a more general model $(\mathrm{GTR}+\Gamma)$ and two selected $\operatorname{Tr} \mathrm{N}+\Gamma$ (very similar to $\mathrm{HKY}+\Gamma[18]$ ).
- GTR was selected in 8 out of 10 test instances for GTR (see Table 0.18 and Table 0.19), while the other two test instances selected GTR $+\Gamma$.

## Contents

Table 0.5: Test results. An asterisk $(*)$ indicates a perfect match; a plus (+) indicates a match, but with a $\Gamma$ rate parameter added; a minus (-) denotes a mismatch of low significance, where the AIC error rate (AIC difference between correct model and selected model / AIC of selected model) was below 0.0005 (all entries marked with a plus also met this criterion); finally, more significant mismatches are indicated by numbers in parentheses with the erroneous choice of model and the corresponding AIC error rate explained as follows: (1)-K2P 0.00113, (2)-TrN 0.00086

| Model tested | test \# | 1 | 2 | 3 | 4 | 5 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| JC | 1 | $(1)$ | $*$ | $*$ | $*$ | $*$ |
|  | 2 | $*$ | $*$ | $*$ | $*$ | - |
| K2P | 1 | $*$ | $*$ | $*$ | $*$ | $*$ |
|  | 2 | $*$ | - | $*$ | + | $*$ |
|  | 3 | + | $*$ | $*$ | $*$ | $*$ |
| HKY | 1 | - | - | $*$ | $(2)$ | $*$ |
|  | 2 | $*$ | - | $*$ | $*$ | + |
|  | 3 | $*$ | $*$ | - | $*$ | $*$ |
|  | 4 | $*$ | - | + | $*$ | + |
| HKY + Г | 5 | $*$ | - | - | $*$ | $*$ |
|  | 6 | $*$ | $*$ | $*$ | - | $*$ |
|  | 7 | - | $*$ | $*$ | $*$ | - |
| GTR | 1 | + | $*$ | $*$ | $*$ | $*$ |
|  | 2 | $*$ | $*$ | $*$ | + | $*$ |
| GTR $+\Gamma$ | 3 | $*$ | $*$ | $*$ | $*$ | $*$ |
|  | 4 | $*$ | $*$ | $*$ | $*$ | $*$ |
|  | 5 | $*$ | $*$ | $*$ | $*$ | $*$ |

- GTR $+\Gamma$ was selected in all 15 test instances for GTR $+\Gamma$ (see Table 0.20 to Table 0.22).

Overall, among 85 test instances, 62 test instances selected the correct models and an additional 8 selected the correct model plus $\Gamma$; in the latter case, the AIC score of the chosen model was within $0.05 \%$ of that the correct model (a difference of less than 3). Among the remaining 15 test instances, the second best model was the correct one in 10 test instances and always with an AIC score within $0.12 \%$ of that of the correct model (a difference of less than 7). In only one test instance did

and Table 0.4).

These tests show that FINDMODEL results are more accurate when the sequences are longer, a common finding in phylogenetic analyses $[2,12]$.

### 0.5.3 Results Regarding $\Gamma$ Rate Heterogeneity

We used $\Gamma$ rate heterogeneity in the testing for two models, HKY and GTR.

- For HKY, AIC values for models with $\Gamma$ were much smaller than AIC values for the corresponding homogeneous model versions; they differed by about $2 \%$ with 5 categories for the discrete $\Gamma$ rate heterogeneity (see Table 0.15 ), by about $15 \%$ for $\Gamma=0.1$ (see Table 0.16 ), and by about $5 \%$ for $\Gamma=0.5$ (see Table 0.17). AIC values were smaller than AIC values in test instances using the same set of parameters but without $\Gamma$ (see Table 0.13); they differed by about $6 \%$ for HKY test5, by about $36 \%$ for HKY test6, and by about $12 \%$ for HKY test7.
- For GTR, AIC values for models with $\Gamma$ were much smaller than AIC values for the corresponding homogeneous model versions; they differed by about $2 \%$ with 5 categories for the discrete $\Gamma$ rate heterogeneity (see Table 0.20 ), by $16 \%$ for $\Gamma=0.1$ (see Table 0.21), and by $5 \%$ for $\Gamma=0.5$ (see Table 0.22 ). AIC values were smaller than those in test instances using the same parameters without the $\Gamma$ rate heterogeneity (see Table 0.19); they differed by about $6 \%$ for GTR test3, by about $40 \%$ for GTR test4, and by about $9 \%$ for GTR test5.

The difference between AIC value for models with and without $\Gamma$ is much larger for $\Gamma=0.1$ than for $\Gamma=0.5$, as one would expect (recall that a smaller $\Gamma$ means more variation in rates). Thus FINDMODEL works correctly with $\Gamma$.
